# Diallel Analysis of Maize Inbreds for Grain Yield, Protein and Tryptophan Content 

Mohamed Ali<br>Agronomy Department, Faculty of Agriculture, Assiut University, Assiut 71526, Egypt.

#### Abstract

ADOPTION of quality protein maize in Egyptian maize breeding programs would maximize the nutritional value of maize products. However, the assessment of adaptability of exotic quality protein maize germplasms is an important step before incorporating them in breeding programs. The current studies consisted of two experiments including a preliminary evaluation of some exotic quality protein maize inbreds and combine eight adapted elite inbreds into a halfdiallel cross. The current study revealed that CML158 exhibited the highest significant general combining ability effect with an average grain yield/plant of 53.0 g . While CML492 contained the highest percentages of both protein (14.5\%) and tryptophan ( $1.02 \%$ ) with the highest values of general combining ability effects. Based on specific combining ability, the best parental combination for grain yield/plant was CML $182 \times$ CML 184 , which yielded 239 g and exceeded the average grain yield/plant of all hybrids ( 201.5 g ). It seems that CML143 possesses favorable alleles for increasing the percentage of protein (CML143 $\times$ CML557) and tryptophan (CML158 $\times$ CML491 and CML143 $\times$ CML182) because it was a common parent in the best parental combinations for both traits. Mid-parent heterosis \% varied from trait to trait; however, the highest amount of heterosis was detected in grain yield/plant due to its polygenic state. In conclusion, superior hybrids in yield and quality were detected. These hybrids need further evaluations across years and locations to assess stability. These hybrids can be considered as a cheap and sustainable source of high protein and tryptophan content for human consumption, which might play a magnificent role in food security in Egypt.

Keywords: Quality protein maize, General combining ability, Specific combining ability, Heterosis.

## Introduction

Maize is the main cereal crop in many parts of the world. Its production is estimated to increase by 161 million ton to 1.2 billion ton by 2027 (OECDFAO, 2018). Maize play a major economic role in both food manufacturing and fresh consumption. As the world population increases, the desire of development of high yielding hybrids resulted in reduction in the nutritional value (e.g., proteins and essential amino acids) caused by the adverse association with yield (Zhang et al., 2008; Bueno et al., 2009). Maize bread is a staple food in most urban and rural areas in Egypt (Galal, 2002). However, maize proteins lack to essential amino acids e.g. tryptophan (Bantte \& Prasanna, 2004). Due to the expensive cost of the supplementary essential amino acids, it is paramount to develop
genetically enhanced maize hybrids with high content of protein and essential amino acids.

Mertz et al. (1964) discovered the opaque-2 mutant gene and its relationship with increase the content of tryptophan in maize, which resulted in developing quality protein maize (QPM). This mutant was transferred to normal maize lines via normal breeding strategies, which led to double the content of tryptophan in maize endosperm (Chaudhary et al., 2014). In addition, the percentages of proteins in QPM lines are higher than non-QPM lines (Prasanna et al., 2001). However, QPM breeding materials are $10-$ $15 \%$ lower in grain yield comparing to non-QPM materials (Vasal, 2014); this is due to different reasons as revealed by Prasanna et al. (2001) and Vasal (2002). Nevertheless, this reduction in grain

[^0]yield in QPM materials can be lessened down via breeding strategies of selection e.g. recurrent selection (Vasal, 2002).

CIMMYT as well as other maize breeding programs worldwide (Brazil, China, USA and India) have adopted the discovery of opaque-2 (Vasal, 2001; Bhatnagar et al., 2004); that unlocked new vistas and effectively participated in food security for humans, and improved growth of farm animals. Lodha (2014) discussed examples of the positive effect of QPM on both animals and humans. For example, animals that were fed on QPM products gained double weight (g) compared to those that were fed on non-QPM (Lodha et al., 1976), in addition, in India, the weight and height of children fed on QPM improved by $25 \%$ and $29 \%$, respectively, compared to those who fed on nonQPM (Singh et al., 1980). Because QPM contains $60-100 \%$ more of tryptophan and lysine comparing to non-QPM, the biological value of QPM is $80 \%$ while non-QPM is $40-57 \%$ (Bressani, 1992).

Screening and adaptability of exotic QPM inbreds and the efficient introducing of such adapted inbreds into breeding programs might increase protein quality and increase genetic variability for selection efficacy (Bhatnagar et al., 2004). Further emphasizes was reported on the importance of exotic QPM inbreds to create genetic variation of maize genetic materials in USA by Goodman et al. (2000).

As Egypt is lagging behind other countries in development of QPM hybrids, the current study is the first trial to adopt QPM and open new vistas to improve Egyptian maize materials and increase nutritional value of maize for both humans and animal. Therefore, it is not only vital to introduce QPM inbred lines into the Egyptian maize germplasm to broaden the genetic base of nutritional value of Egyptian germplasm, but also enhance the adaptability of new hybrids to the Egyptian climatic and edaphic conditions. Consequently, the assessment of combining ability of these QPM inbred lines on grain yield and quality is paramount.

The initial evaluation of exotic QPM inbreds is a vital step to conclude their breeding potential (Geadelmann, 1984). Diallel crosses between adapted elite exotic QPM inbred plays an important role in determining the heterotic interactions among QPM inbreds, which leads to identify the best hybrids (Bhatnagar et al., 2004). Griffing's diallel
analysis (Griffing, 1956) partitioned the sum of squares of genotypes (parents and their $\mathrm{F}_{1}$ crosses) into sum of squares due to general combining ability (GCA), which represents the additive effect and sum of squares due to the specific combing ability (SCA), which symbolizes to the non-additive constitute. This elucidates the genetic control of traits of interest (Werle et al., 2014). Therefore, the objectives of the present study were to: i) evaluate exotic QPM inbreds under Egyptian environmental conditions as an initial step to ensure adaptability, high productivity and quality, ii) assess GCA effects for grain yield and quality as well as other agronomic traits, and iii) estimate SCA effects to recognize the superior hybrids combinations.

## Materials and Methods

## Plant materials and growing conditions

A set of 49 white maize inbred lines obtained from CIMMYT including 40 QPM inbred lines and nine non-QPM inbred lines (Table 1) were assessed during the summer seasons of two years (2016 and 2017) at Assiut University Agricultural Research Station (AUARS). Eight elite QPM inbred lines were chosen and their non-reciprocal $F_{1}$ hybrids were produced during late season of 2017. During the summer season of 2018, the eight elite parental QPM inbred lines and their non-reciprocal $F_{1}$ hybrids (half-diallel) were evaluated at AUARS. The current study was performed in a clay soil. Irrigation, fertilization and other cultural practices were carried out as recommended for optimum maize production.

The preliminary experiment of 49 QPM inbred lines for the two growing seasons and the halfdiallel experiment were evaluated in a complete randomized block design with three replications. Each inbred line or $\mathrm{F}_{1}$ hybrid was sown in a 6 -meter long row with inter-row space of 0.6 m and the distance among plants was 0.20 m .

## Studied traits

Flowering traits
Days to $50 \%$ anthesis (DA; days) were calculated as number of days from sowing until $50 \%$ of the plants in each row showing at least one anther from the tassel. Days to $50 \%$ silking (DS; days) were calculated as number of days from sowing until $50 \%$ of plants in each row showing silks. Anthesis-silking interval (ASI; days) computed as the difference between days to $50 \%$ anthesis and silking.

+Non-QPM inbred lines.

## Morphological traits

Plant height ( $\mathrm{PH} ; \mathrm{cm}$ ) was measured as the distance from the soil surface to the top of tassel. Ear height $(\mathrm{EH} ; \mathrm{cm})$ was measured as the distance from the soil surface to the main ear bearing node.

Grain yield per plant (GYP; g) was recorded at harvest by dividing the grain yield of each row by the number of plants per row.

## Quality traits

Protein content ( $\mathrm{mg} / 100 \mathrm{mg}$ flour): the total protein content in endosperm of grains was assessed using Micro-Kjeldahl digestion (AOAC, 1965). The
protein content in the endosperm was estimated based on the nitrogen percentage as per Moro et al. (1996) and Kassahun (2001).

Tryptophan content in protein (mg/ 100 mg protein): the tryptophan content was estimated using the colorimetric method as per Herbabdes \& Bates (1969).

## Statistical analyses

Separate and combined analysis of variance over two growing seasons of the preliminary experiment of assessing 49 inbred lines were accomplished using PROC GLM procedure (SAS
v9.0, SAS Institute Inc., Cary, NC, USA, 2003). The $28 \mathrm{~F}_{1}$ hybrids were analyzed using Griffing's method 4 (Griffing, 1956) via AGDR-R version 4 (Rodríguez et al., 2015).
 narrow-sense heritability $\quad\left(\mathrm{h}_{\mathrm{n}}=\frac{\sigma_{a}^{2}}{\sigma_{\mathrm{p}}^{2}}\right) \quad$ were estimated as per Zhang \& Kang (1997) assuming no epistasis. Where, $\sigma_{g}^{2}=2 \sigma_{g c a}^{2}+\sigma_{s c a}^{2}$, and

$$
\sigma_{p}^{2}=2 \sigma_{g c a}^{2}+\sigma_{s c a}^{2}+\sigma_{\text {error }}^{2} \sigma_{a}^{2}=2 \sigma_{g c a}^{2}
$$

Mid-parent Heterosis \% for each $\mathrm{F}_{1}$ hybrid was calculated as the difference between the $F_{1}$ hybrid mean $\left(\bar{F}_{1}\right)$ and the average of the two parental inbred lines (MP) as the following:

$$
\text { Heterosis }=\frac{\overline{\mathrm{F}}_{1}-\mathrm{MP}}{\mathrm{MP}} \times 100
$$

## Results

## Mean performance of inbreds

Mean performance of all traits based on separated years and combined overall years are presented in Tables 2 and 3. In general, QPM inbreds were superior over non-QPM inbreds on their content of both protein and tryptophan. Eight elite QPM inbred were selected based on their performance over two years to develop halfdiallel $\mathrm{F}_{1}$ hybrids. These inbreds included CML \# $143,155,158,182,184,491,492$ and 557.

Based on analyses of variance for the preliminary experiment, inbred lines showed significant differences for all traits in both separated and combined analyses (Tables 4 and 5). Similarly, the interaction between inbred lines and years was significant except for DS and ASI. Years had significant effect on only three traits (EH, protein and tryptophan).

The mean performance of all traits for parental inbreds and their $28 \mathrm{~F}_{1}$ hybrids are presented in Table 6.

## Mean square estimates

Significant differences were observed among $\mathrm{F}_{1}$ hybrids for all traits (Table 7). The means of DA and DS of $F_{1}$ hybrids were 6.49 and 6.21 days, respectively, earlier than the mean of parental
inbreds. The mean of PH and EH of $\mathrm{F}_{1}$ hybrids exceeded the mean of parental inbreds with 93.42 and 57.39 cm . The mean GYP for $\mathrm{F}_{1}$ hybrids was more than triple of mean of parental inbreds. Nevertheless, the mean protein percentage of $F_{1}$ hybrids did not exceed the mean of parental inbreds unlike tryptophan percentage. Significant differences among both GCA and SCA effects were detected for all traits. In addition, the mean square values of GCA were higher than SCA for all traits.

## Heritability

Broad-sense heritability values were high for all traits except ASI; whereas, narrowsense heritability showed poor value for ASI, moderately low values for PH, EH, GYP and tryptophan, and high for the rest of traits. More details about heritabilities can be found in Table 7.

## General combining ability (GCA) effects

The GCA effects are shown in Table 8. The GCA effects showed significant differences for all parental inbreds for DA except for CML158. CML557 and CML182 showed the highest and the smallest GCA effect, respectively, for DA. Regarding DS, all parental inbreds showed significant differences for their GCA effects except for CML143, 155 and 158. CML182 showed the smallest GCA effect unlike CML557. Only three parental inbreds (CML155, 184 and 557) showed significant differences for ASI. The desirable negative effect of GCA effect was found in CML182 indicating its earliness of flowering. For PH, all parental inbreds showed effects of their GCA effects except CML155, 182, 184 and 491. CML158 showed the highest GCA effect, whereas CML557 showed the smallest GCA effect. In addition, for EH, all parental inbreds showed significant GCA effects except for CML182 and 557. The CML184 showed the highest significant effect of GCA unlike CML143. For GYP, all parental inbreds showed significant differences for their GCA effect. CML158 showed the highest GCA effect while CML143 showed the smallest GCA effect. Regarding the grain quality traits, the GCA effects for all parental inbreds were significant for percentage of protein, where CML492 showed the highest GCA effect while CML155 showed the smallest GCA effect. For percentage of tryptophan, CML492 showed the highest GCA effect unlike CML158.

Specific combining ability (SCA) effects
The detailed SCA effects of $\mathrm{F}_{1}$ hybrids for all traitsareshowninTables9-12. Briefly, theearliest $\mathrm{F}_{1}$ hybrid based on anthesis was CML155×CML491 (58 days) with the smallest significant SCA effect (SCA $=-5.04$ ), while CML143 $\times$ CML491 was the earliest $\mathrm{F}_{1}$ hybrid to silk ( $\mathrm{SCA}=-4.78$ ) with 59 days followed by CML $155 \times$ CML491.

The maximum significant SCA effect for ASI was found in CML182 $\times$ CML184 $(S C A=0.98)$. Hybrid CML158 $\times$ CML557 showed the highest significant SCA effect for $\mathrm{PH}(\mathrm{SCA}=16.55)$, while hybrid CML143 $\times$ CML184 exhibited the highest significant SCA for $\mathrm{EH}(\mathrm{SCA}=5.88)$. For GYP, CML182 $\times$ CML184 showed the highest significant positive SCA effect $(\mathrm{SCA}=33.40)$
with highest GYP ( 239 g ) which was higher than the average GYP for all $\mathrm{F}_{1}$ hybrids $(201.5 \mathrm{~g})$. In general, GYP showed the highest SCA effects among studied traits. For percentage of protein, CML143 $\times$ CML557 showed the highest SCA effects $(S C A=2.61)$ with $14 \%$, which exceeded the mean percentage of protein (11\%) for all $\mathrm{F}_{1}$ hybrids. While CML158×CML491showed the highest SCA effect $(S C A=0.11)$ with percentage
of tryptophan $=1.06 \%$. In addition, the second most promising hybrid in terms of percentage of tryptophan was CML143 $\times$ CML182 $(\mathrm{SCA}=0.09)$ with $1.03 \%$. Both hybrids exceeded the mean percentage of tryptophan (1\%) for all hybrids. The presence of CML143 in the best hybrids in terms of percentages of protein and tryptophan showed that this parental inbred possessed favorable alleles for increasing both protein and tryptophan.

## Heterosis estimates

The Mid-parent heterosis \% of all traits for 28 $\mathrm{F}_{1}$ hybrids is presented in Table 13. Briefly, the mid-parent heterosis \% for DA and DS ranged from $5.49 \%$ for hybrid (CML143 $\times$ CML492) to $-25.40 \%$ for hybrid (CML155×CML184). For GYP, it ranged from $96.84 \%$ in hybrid
(CML182×CML492) to $472.39 \%$ for hybrid (CML143 $\times$ CML158). For protein \%, it ranged from $-21.41 \%$ for hybrid (CML155×CML557) to $21.39 \%$ for hybrid (CML143×CML557), while for tryptophan $\%$, it ranged from $-9.47 \%$ for hybrid (CML155×CML182) to $24.87 \%$ for hybrid (CML158×CML491).

## Discussion

As the mean square values of GCA were higher than SCA for all traits, this indicates the importance of additive gene action. These results were consistent with San Vicente et al. (1998) and Bhatnagar et al. (2004) who revealed the importance of gene action in breeding programs. The ratio of additive to non-additive constituents gives an idea about the gene action (Baker, 1978). The additive gene action was predominant in CIMMYT's QPM hybrids that enhanced grain
yield (Vasal et al., 1993), which is consistent with the results of the current study. The negative effects of GCA effect for inbred CML492 (60 days; for DA) indicated its earliness of flowering and its adaptability to Egyptian environment. Bhatnagar et al. (2004) detected CML184 as the earliest inbred in flowering traits, while, in the current study, CML184 ( $\approx 74$ days, DA) showed medium time of flowering. This result is inconsistent with those found by Bhatnagar et al. (2004). This could be due to differences in adaptability between USA and Egypt.

The most promising parental combination for GYP was CML184×CML182. In this regard, the current outcome is consistent with the findings of Bhatnagar et al. (2004) who found that CML184 is one parental line for most yielding $\mathrm{F}_{1}$ hybrids. In the current study, very high effects of SCA have been detected for GYP; this indicates that potential improvement of GYP can be expected. This is consistent with the conclusions of Glover et al. (2005) when they used adapted exotic germplasm in diallel analyses.

The current results showed high divers amount of heterosis \% from trait to trait. This is due to the
genetic basis of each trait-dependent (Flint-Garcia et al., 2009). In addition, heterosis for GYP was higher than other traits. Flint-Garcia et al. (2009) found similar results when they compared heterosis of yield and its components. This is because yield and its components are complex traits (Lippman \& Zamir, 2007). In their study about heterosis in different maize inbreds, FlintGarcia et al. (2009) reported positive associations between genetic distance and heterosis. However, Melchinger (1999) indicated that the genetic distance is not a good indicator of heterosis for grain yield. The current study supports latter statement.

TABLE 13. Mid-parent heterosis as \% for studied traits in 28 maize single-cross hybrids.

- DA= Days to $50 \%$ anthesis (days), DS = Days to $50 \%$ silking (days), $\mathrm{ASI}=$ Anthesis siliking interval (days), $\mathrm{PH}=\mathrm{Plant}$ height (cm), EH= Ear height (cm), GYP= Grain yield per plant (grams), protein= Protein content ( $\mathrm{mg} / 100 \mathrm{mg}$ flour) and tryptophan= Tryptophan content in protein ( $\mathrm{mg} / 100 \mathrm{mg}$ protein).

## Conclusion

The adoption of incorporation of adapted exotic QPM inbreds from diverse backgrounds in the Egyptian maize breeding programs will lead to develop QPM hybrids. This study aims to unlock doors for new and promising vistas to benefit from exotic QPM germplasm in enhancing the nutritional value of Egyptian maize as cheap
and sustainable sources of increasing proteins and essential amino acids, e.g. tryptophan. In the current study, I identified superior hybrids in grain yield and quality. Further evaluation of these hybrids should be performed under different locations across Egypt and for many years to guarantee stability and ensure tolerance to biotic and abiotic stresses.
